ABSTRACT

In this method to amounting of the trace amount of Cu (II) ions in aqueous Samples by CNT modified Amino-pyrrolidine dithiocarbamate (APDC) which in order to improve the performance of extraction and preconcentration was used. Amounting of the ions density in solution was performed by the method of flame atomic absorption spectrometry. The effective parameters on extraction such as: effect of pH, the amount and eluent solvent, time of extraction and effect of other cation were optimized. Concentrate factor was found 57 and LOD method of limit of detection was found to 0.6µg.L⁻¹. the relative standard deviation is 0.76% (RSD%).

Keywords: Copper(II), Preconcentration, Amino-pyrrolidine dithiocarbamate (APDC), extraction, carbon nanotubes, FAAS.

INTRODUCTION

Copper at trace concentrations acts as both a micronutrient and a toxicant in marine and fresh water systems. This element is needed by plants at only very low levels and is toxic at higher levels. At these levels, copper can bind to the cell membrane and hinder the transport process through the cell wall. Copper at nearly 40ng mL⁻¹ is required for normal metabolism of many living organisms. On the other hand, copper is an important element in many industries. Thus, the development of new methods for selective separation, concentration and determination of it in sub-micro levels in different industrial, medicinal and environmental samples is of continuing interest. The determination of copper is usually carried out by flame and graphite furnace atomic absorption spectrometry (AAS) as well as spectrometric methods. However, due to the presence of copper in medicinal and environmental samples at low levels, its separation from other elements presents and
also the use of a preconcentration step prior to its determination is usually necessary.

Different methods, especially Liquid-liquid extraction of copper in the presence of various classical and macrocyclic co-extractant ligands has attracted considerable attention. However, the use of classical extraction methods for this purpose is usually time-consuming, labor-intensive and requires large amounts of high purity solvents for extraction. Nevertheless, several other techniques for the preconcentration and separation of copper have been proposed including liquid chromatography, supercritical fluid extraction, flotation, aggregate film formation, liquid membrane, column adsorption of pyrocatechol violet-copper complexes on activated carbon, ion pairing, preconcentration with yeast, and solid phase extraction using C18 cartridges and disks.

Solid phase extraction (SPE) or liquid-solid extraction is popular and growing techniques that are used to sample preparation for analysis. It is an attractive alternative for classical liquid-liquid extraction methods that reduce solvent usage and exposure, disposal costs and extraction time for sample separation and concentration purposes.

Chitosan has been reported to be a suitable biopolymer for the removal of heavy metals from industrial wastewater, due to its high amino and hydroxyl functional group content, low toxicity, biocompatibility, and biodegradability. However, to improve its absorption capacity and enhance the separation rate, the design and synthesis of novel adsorbents are still critical.

Fig. 1: SEM image of Multi walled carbon nanotubes (SWCNTs)

Fig. 2: Raman Spectroscopy of Multi walled carbon nanotubes (MWCNTs)
application of magnetic adsorbent technology to solve environmental problems is a relatively new and emerging field of research. Coating chitosan with magnetic fluids is a new method to improve separation speed, and the method has been reported that it can improve the surface area for adsorption and reduce the required dosage for the adsorption of heavy metals.

Actually, the SPE technique using graphene and derivatives of graphene such as functionalization graphene oxide as a novel and great adsorbent. This present work preconcentration of Cu$^{2+}$ based on the adsorption of its Ammonium Pyrrolidine Dithiocarbamate (APDC) complex on an MWCNTs. The adsorbed complex could be eluted using environmentally and the concentration of Cu$^{2+}$ was determined by FAAS. The influence of various experimental parameters such as acidity, sample volume, flow rate, diverse ions, etc. was examined in detail. The validity of the proposed method was tested in tap water samples and waste water.

**EXPERIMENTAL**

**Instrumentation**

Determination of Cu$^{2+}$ by PG-990 flame atomic absorption spectrometer equipped with HI-HCl according to the recommendations of the manufacturers. These condition are tabulated in (Table 3). The pH measurements used by Sartorius model PB-11.

**Chemicals and reagents**

Multi walled carbon nanotubes (MWCNTs), Schiff’s Ammonium Pyrrolidine Dithiocarbamate (APDC) were prepared from Darmstadt, Germany of Merck, Method and dried for a week over phosphorus pentoxide in a vacuum desiccators before use. 4-Isocyanatobenzenesulfonyl azide was prepared from 4-carboxybenzenesulfonyl

azide via a published procedure\textsuperscript{17}. All solutions were prepared with doubly distilled deionized water from Darmstadt, Germany of Merck. C\textsubscript{18} powder for chromatography with diameter of about 50 µm obtained from Katayama Chemicals from Supelco. It was conditioned before use by suspending in 4 M nitric acid for 20 min, and then washed two times with water.

**Preparation of Multi walled carbon nanotubes (MWCNTs) cartridge**

A column 1.5 cm in diameter and 15 cm in length was used for the preconcentration of Copper(II). About 5 g of Multi walled carbon nanotubes cartridge was mixed with 25mL of HCl 1M to form slurry and then loaded on to the column. Cotton was placed at the bottom for allowing Multi walled carbon nanotubes (MWCNTs) cartridge to settle properly. The column was packed up to a height of 3 cm.

**Procedure for present method**

30 mg Ammonium Pyrrolidine Dithiocarbamate(APDC) and 50mg SDS of 50mL was loaded on to the column of neutral Multi walled carbon nanotubes (MWCNTs) cartridge maintaining a flow rate of 8mL min\textsuperscript{-1}. Then 10 µg Cu(II) solution of 250 ml volume was loaded on to the column. The sample solution was uploading on to the column of neutral Multi walled carbon nanotubes (SWCNTs) cartridge maintaining a flow rate of 0.5mL min\textsuperscript{-1}. The desorption complex and eluted using 10mL of HNO\textsubscript{3} 4M at a flow rate of 0.5mL min\textsuperscript{-1} and the concentration of Copper(II) was determined by FAAS.

RESULTS AND DISCUSSION

Fig. 1. show the morphology and size of Multi walled carbon nanotubes (MWCNTs) modified by Ammonium Pyrrolidine Dithiocarbamate(APDC) sorbent as shown in Fig. 1. sorbent retained a homogenous distribution in the range of 156.0–10.0 nm. Fig.2. The formation of MWCNTs was followed by Raman Spectroscopy spectroscopy. The carbonyl vibration appears at 1580 cm⁻¹, while there are fingerprints at 160 cm⁻¹ and 230 cm⁻¹ due to the presence of hydroxyl species at the carbon nanotubes.

Factor of pH in Preconcentration

The factor of pH of the aqueous solution on the extraction of 100 ng of each of the cations Cu(II) was studied in the pH rang of 1-10. The effect pH of the solution was adjusted by means of either 0.01 M HNO₃ or 0.01M NaOH. The best of recovery was obtained indicate that complete chelation and recovery of Cu(II) occurs in pH range of 6-8 and that of in 2-9 and are shown in Fig. 3. It is probable that at higher pH values, the cations might be hydrolysed and complete desorption occur. Hence, pH=8.0 in order to prevent hydrolysis of the cations and also keeping on the cartridge C₁₈, was chosen for further research.

Choice of the eluent

A reagents were tested in order to desorption complex from the column. In order to choose the most effective eluent for the quantitative recovery of Copper(II), methanol, ethanol, acetone, HCl 1M, HCl 3M, H₃PO₄ 1M, and Acidified solvents obtained by addition of HNO₃ 4M, were studied. The recovery of Copper(II) was found to be quantitative with ethanol and HNO₃ 4M as eluting agents. However, HNO₃ 4M was preferred owing to its non-inflammability and less toxicity. It was observed that when the ratio of HNO₃ 4M a recovery of 99.8%.

Effect of sample volume

The recovery of the analyte was researched in the range 100–1500mL maintaining an overall

concentration of 0.025 mol L⁻¹ sulfuric acid. The resulting complex was eluted using 10mL of HNO₃ 4M. As can be seen from the figure, it is evident that the recovery of copper(II) is more than 97% up to 250mL sample volume. A preconcentration factor of 57 could be attained for more than 97% of Cu(II) when the sample volume was 250 mL.

**Effect of flow rate**

The flow rate suitable for optimum loading of Cu(II) Ammonium Pyrrolidine Dithiocarbamate (APDC) complex on the Multi walled carbon nanotubes (MWCNTs) cartridge. This could be probably due to the insufficient contact time between the sample solution and Multi walled carbon nanotubes (MWCNTs) cartridge. A flow rate of 5mL min⁻¹ was maintained for the elution of copper(II) Fig 4.

**Precision studies and limit of detection**

Under optimized conditions, a calibration curve for Cu (II) was found by preconcentrating a series of Cu (II) standards according to the procedure mentioned. The curve was linear from 1.0 mg/l to 7.0 mg/l for Cu. As analytical figures of merit, The limit of detection was found to be 0.1µg.mL⁻¹.

**Effect of foreign ions**

The influence of common foreign ions on the adsorption of Cu (II) on CNT modified Amino-pyrrolidine dithiocarbamate (APDC) were studied. In these work, 50.0 ml solutions containing 5ppm of Cu and various amounts of interfering ions were treated according to the suggested procedure. The tolerancy level was defined as the maximum concentration of the foreign ion causing a change in the analytical signal no higher than 5%, when compared with the signal of 5ppm copper alone. The results, listed in Table 1 demonstration that the presence of major cations and anions in natural water has no important influence on the adsorption of Cu (II) ions under the designated conditions.

**Recovery studies in real sample**

The accuracy of the proposed method was tested by spiking known concentrations of copper(II) to tap water (Tehran, taken after 10 min operation of the tap), and rain water (Tehran, 21 Jun, 2016) samples. The water samples were filtered and stored in PET bottles. The recovery of Copper(II) was found to be satisfactory with a relative standard deviation of 5% for 3 replicate measurements and the results are shown in Table 2.

**Comparison with other solid phase adsorbents**

The present method was compared to a variety of solid adsorbents reported recently in the literature. Also, the proposed method was free of interference compared to conventional procedures to determine Copper⁴⁶,⁵¹,⁵². As can be seen from the references, it is evident that the preconcentration factor obtained with Multi walled carbon nanotubes (MWCNTs) cartridge is comparable to or even better than most of the other chelating matrices. The significant feature of the proposed method is the use of water samples benign HNO₃ 4 M for the elution of the complex.

**Calibration curve**

The calibration curve of Copper(II) solutions is represented in Fig.5 and the related regression is \( Y = 0.0022X + 0.0228 \) providing a correlation coefficient of \( R^2 = 0.9996 \).

**CONCLUSIONS**

The proposed SPE method possesses advantages such as easiness, and considerable selectivity in comparison with the previously reported procedures for isolation and determination of Cu²⁺ contents⁴⁶,⁵¹,⁵². In conclusion, the proposed SPE possesses the following advantages: the technique is rapid when compared with the previously reported procedures for the separation and determination of copper, the time taken for the separation and determination of copper in a 500 mL sample is at the most 30 min. Furthermore, it is a simple, highly sensitive, selective and reproducible method for the separation of Cu²⁺ and in this work the recovery yields obtained with CNT modified Amino-pyrrolidine dithiocarbamate (APDC) were about 95-100% then it show derivation e.g. in this work CNT modified Amino-pyrrolidine dithiocarbamate (APDC) is full of potential for use as a adsorbent in the extraction method like SPE and SPME consequently it can be applied to the preconcentration and determination of copper and the large number of heavy metal that are dangers for human from real samples.
