ABSTRACT

The interaction of Mn (II), Co (II), Ni (II), Cu (II) and Zn (II) metal ions with levodopa (LDP) and methyldopa (MDP) have been studied by pH-metric technique at 0.1 M (KNO₃) ionic strength at 302 ± 0.5 K in aqueous medium. The data obtained were used to evaluate the values of proton-ligand and metal-ligand stability constants using Irving-Rossotti titration technique. Mixed ligand complex studies of these metal ions using aspartic acid (ASP) and glutamic acid (GLU) as primary ligands and LDP and MDP as secondary ligands also have been carried out pH-metrically at the same conditions.

Key Words: Ternary complexes, Transition metal ions, levodopa, aspartic acid and glutamic acid.

INTRODUCTION

Recently, there has been considerable interest in the study of binary, ternary and quaternary complexes by pH-metric method¹-³. The ligand levodopa (LDP) is well known for its use in neurotransmission process⁴ and the treatment of Parkinson disease⁵. The ligand methyldopa (MDP) is an antihypersensetive agent which has a depressant action on the central nervous system⁶-⁸.

Ternary complexes of Ni (II) and Cu (II) with nicotinic acid as primary ligand and imidazoles, benzimidazole, histamine and L-histididine as secondary ligands have been studied by Nair and Neekantan⁹. Patil and Mhaske ¹⁰ have studied the stability constants of Mn (II), Co (II), Ni (II), Cu (II) and Zn (II) with nitrilotriacetic acid and Iminodiacetic acid as primary ligands and levodopa and methyldopa as secondary ligands potentiometrically. Nigam and coworkers¹¹ have studied the ternary complexes of Mn (II), Co (II), Ni (II), Cu (II) and Zn (II) with thymine as secondary ligand potentiometrically. Ternary complexes of Cu (II) using ASP and GLU as primary ligands have been reported potentiometrically by Pandeya and Patel¹². Kalshetti
Turner, Anderson et al., and coworkers have studies binary and ternary complexes of Co (II), Ni (II), Cu (II) and Zn (II). Mixed ligand complexes of transition metal(II) ions with N-(2-hydroxybenzylidene)-2,3-dimethylaniline as primary ligand and N-(2-hydroxy-1-naphthylidene)-4-chloroaniline as secondary ligand has been studied by Mapari and Mangaonkar. Solution equilibria of ternary systems involving transition metal ions, hydroxamic acids, and bioligands have been studied by Khalil and Mahmoud.

In this paper the stability constants of ternary complexes of Mn (II), Co (II), Ni (II), Cu (II) and Zn (II) ions with ASP and GLU as primary ligands and LDP and MDP as secondary ligands at 302 ±0.5 K and at fixed ionic strength, µ = 0.1M KNO₃ using modified form of Irving-Rossotti pH-metric technique in aqueous medium have been studied.

EXPERIMENTAL

The ligand LDP was obtained from Loba Chemie and MDP was Merind Limited. These ligands were used as such. Carbonate free sodium hydroxide solution was prepared by standard method. All other solutions were prepared in doubly distilled water.

The pH-metric measurements were carried out by using Elico digital pH-meter model L-120 with combined glass-calomel electrode with an accuracy of ± 0.01 of pH unit at 302 ± 0.5 K. The pH-meter was standardized against 0.05 M potassium hydrogen phthalate solution in acid medium and 0.01M borax solution in alkaline medium.

For determination of proton-ligand stability constant of the secondary ligand and the metal-ligand stability constants of ternary complexes, the following set of solutions were prepared and titrated against standard alkali solution.

Ternary Systems

\[
\begin{align*}
\text{i)} & \quad 9.6 \times 10^{-3}\text{M HNO}_3 \\
\text{ii)} & \quad 9.6 \times 10^{-3}\text{M HNO}_3 + 1.0 \times 10^{-3}\text{M secondary ligand} \\
\text{iii)} & \quad 9.6 \times 10^{-3}\text{M HNO}_3 + 1.0 \times 10^{-3}\text{M primary ligand} \\
\text{iv)} & \quad 9.6 \times 10^{-3}\text{M HNO}_3 + 1.0 \times 10^{-3}\text{M primary ligand} + 1.0 \times 10^{-3}\text{M secondary ligand}
\end{align*}
\]

The ionic strength was maintained constant (0.1M) by adding required volume of 1M KNO₃. The ratio of metal (M): primary ligand (A): secondary ligand (L) was maintained at 1: 1: 1 in each of the ternary system.

RESULTS AND DISCUSSION

Proton-Ligand Stability Constants

The plots of volume of alkali (NaOH) against pH-meter readings were used to evaluate the proton-ligand stability constants of LDP and MDP. The deviation between free acid titration curve and secondary ligand titration curve was used to evaluate the formation functions \( \beta \). The proton-ligand formation curves were then obtained by plotting the values of \( \beta \) versus pH-meter readings. From the graphs, the values of \( \log \beta \) were evaluated by half integral method (method A) and point wise calculation method (method B) and presented in Table 1.

Metal – Ligand Stability Constants of Ternary Complexes

The metal – ligand stability constants of the ternary complexes were evaluated assuming that the formation of hydrolyzed products, polynuclear complexes, hydrogen and hydrogen bearing complexes were absent. An examination of titration curves indicates that complex formation has taken place in the solution on the following grounds:

1. The ternary complex titration curves show the displacement with primary complex titration curves. The horizontal distance was measured between acid curve and the secondary ligand curve \( (V_2 - V_1) \) and subtracted through the horizontal distance between ternary complex curves and primary complex titration curves \( (V_4 - V_3) \) show the positive difference which proves the earlier released of protons in the formation of ternary complexes.

2. The hydrolysis of the metal ions was suppressed and precipitation did not result.
The values of \( \bar{n} \) vary from 0 to 1.0, thus confirming the formation of 1:1:1 mixed ligand complexes. The values of \( \log K^H_1 \) and \( \log K^H_2 \) have been evaluated from the formation curves (vs. pL). At \( \bar{n} = 0.5 \) in the formation curve, pL = \( \log K \). The metal-ligand stability constant of LDP as secondary ligand and ASP and GLU as primary ligand are presented in Table 2.

The Irving-Williams order\(^{20-21} \) of stability constants was observed in ternary complexes which is

\[ \text{Mn (II)} < \text{Co (II)} < \text{Ni (II)} < \text{Cu (II)} > \text{Zn (II)} \]

This sequence of stability of complexes with respect to metal ion is due to deceasing atomic radius and increasing the second ionization potential.
