INTRODUCTION

In recent years the complexes of Schiff bases are considered to an important class of chemical compounds used as extensively for the treatment of several diseases1-4. Schiff base complexes have been widely used as analytical reagents5-7 and as corrosion inhibitors8. Keeping the above applications of Schiff base complexes and in continuation of our earlier work9-16 on the Schiff base complexes, preparation and characterization of cobalt(II), nickel(II) and copper(II) complexes with 2,6-dimethyl 4-pyrone semicarbazone are reported here.

EXPERIMENTAL

All the chemicals used were of analytical grade. The complexes were analysed for metal contents by standard procedure17. IR spectra of ligand and their complexes were recorded on Perkin-Elmer 577 using KBr disc. The electronic spectral data were recorded on a Cary 2390 spectrophotometer. Magnetic susceptibility values were measured by Gouy method using Hg[Co(NCS)₄] as a calibrant. The molar conductance measurements were done on systronics conductivity meter model 303 using DMF as the solvent. Analytical data, electronic spectral data, molar conductance value, magnetic susceptibility value, decomposition temperature and molecular formula of the ligand as well as their complexes are recorded in Table – 1 and the salient features of IR bands are recorded in Table 2.

Preparation of the Ligand

Ethanolic solution of 2,6-dimethyl 4-pyrone (0.01M) was treated with semicarbazide hydrochloride (0.01M) dissolved in ethanolic solution of sodium acetate in tetrahydrofuran. The resulting mixtures were heated on water bath for 4 h with frequent stirring. The precipitate was filtered. Washed with ether. The residue was washed with water and recrystallized with DMF. m.p-117±1°C. Yield 70-75%

Preparation of the Complexes

The complexes of cobalt(II), nickel(II) and
copper(II) have been prepared by reacting an ethanolic solution of the ligand 2-6 dimethyl 4-pyrene semicarbazone (DMPS) with ethanolic solution of the corresponding metal halide/nitrate/perchlorate in the molar ratio 2:1 the procedure carried out in each case was of similar nature with a slight variation of timing of reflux. The complexes obtained in each case were washed with ethanol to remove any excess of the ligand. Finally complexes were washed with anhydrous diethyl ether and dried in air oven. Yield 60-65%.

RESULTS AND DISCUSSION

I.R. Spectra, It is established from the literature\textsuperscript{18} that semicarbazone ligand can coordinate in a bidentate manner in most cases through azomethine nitrogen and carbonyl oxygen of semicarbazone moiety.

IR spectrum of the ligand DMPS exhibits a medium broad band at 3220 cm\textsuperscript{-1} assigned\textsuperscript{18,20} to \(V_N-H\). In the spectra of the complexes this band appears without any change indicating that either primary amino or secondary amino groups has not taken part in the coordination with metal ion.

IR spectrum of the ligand exhibits a sharp strong band at 1690 cm\textsuperscript{-1} assigned\textsuperscript{19,21} to \(\nu_{c=o}\). In the spectra of the complexes this band is shifted to higher frequency region and appear at 1725 cm\textsuperscript{-1} with slightly reduced intensity. The shift of the band and change in intensity suggests coordination through carbonyl oxygen of semicarbazone moiety. The linkage with oxygen atom is further supported by the appearance of a new band in the far ir region at 570-520 cm\textsuperscript{-1} in the complexes assignable\textsuperscript{19,22} to \(\nu_{m-o}\). The IR spectrum of the ligand exhibit a band at 1475 cm\textsuperscript{-1} assigne\textsuperscript{19,23} to \(\nu_{c=o}\) in the spectra of the complexes this band shows red shift with slightly reduced intensity. The shift of the band and change in intensity proposes coordination of azomethine N with metal ion. The linkage with nitrogen atom is further supported by the appearance of a band in the far ir region at 395-360 cm\textsuperscript{-1} assigned\textsuperscript{24} to \(\nu_{M-N}\) the evidence of metal halogen is confirmed by the low molar conductance of the complexes in the range 1.1-4.2 ohm\textsuperscript{-1} cm\textsuperscript{2} mol\textsuperscript{-1}. This statements is further confirmed by the apperaence of a band in far ir region at 325-270 cm\textsuperscript{-1} which assigned to \(\nu_{M-X}\).

Nitrate complexes shows characteristic medium intensity bands at 1375 and 1205 cm\textsuperscript{-1} with a separation of about 170 cm\textsuperscript{-1} due to monodentately coordinated nitrate group. Combination band at 1640 cm\textsuperscript{-1} and 1620 cm\textsuperscript{-1} with a separation of 20 cm\textsuperscript{-1} confirming the monodentate behaviour of the nitrate group. In the case of perchlorate complexes four bands are observed at 1150 1050, 650 and 600 cm\textsuperscript{-1} suggesting monodentate coordination of perchlorate group.

Electronic spectra and magnetic susceptibility of the complexes

The electronic spectra of all the complexes have been recorded in the range 10,000-25,00 cm\textsuperscript{-1}, the copper complexes exhibits two broad bands.

DT = Decomposition Temperature
bands in the region 11500-11100 cm\(^{-1}\) and 14800-14400 cm\(^{-1}\) assigned to \(2T_{2g}(F)\) \(\rightarrow\) \(4E_{g}\) and charge transfer bands respectively indicating distorted octahedral geometry for the copper(ii) complexes. The magnetic moment values for copper(ii) complexes, i.e. in the range 1.81 to 1.94 B.M. the cobalt(ii) complexes exhibit three bands in the region 13800-12400 cm\(^{-1}\), 19700-19200 cm\(^{-1}\) and 22640-22100 cm\(^{-1}\) assignable to \(4T_{2g}(F)\) \(\leftrightarrow\) \(4T_{1g}(F)\), \(4A_{2g}(F)\) \(\rightarrow\) \(4T_{1g}(F)\), and \(4T_{1g}(P)\), \(4T_{1g}(P)\) \(\leftrightarrow\) \(4T_{2g}(P)\) respectively. The above mentioned spectral bands indicate octahedral geometry for the cobalt(ii) complexes. The octahedral geometry of cobalt(ii) complexes is also supported by magnetic susceptibility values in the range 4.92 to 5.9 B.M. The nickel (ii) complexes exhibits three absorption bands in the region 10700-10,000 cm\(^{-1}\), 16000 - 15100 cm\(^{-1}\), and 24800-24200 cm\(^{-1}\), respectively assignable to \(3T_{2g}(F)\) \(\leftrightarrow\) \(3A_{2g}(F)\), \(3T_{1g}(F)\) \(\leftrightarrow\) \(3A_{2g}(F)\), and \(3T_{1g}(P)\), \(\leftrightarrow\) \(3T_{2g}(P)\) transitions respectively. The suggesting octahedral geometry for Ni(ii) complexes is further supported by magnetic susceptibility values of the complexes in the range 3.11 B.M. to 3.19 B.M.

### Conductivity Measurement

Molar conductance values of the complexes of cobalt(ii) nickel(ii) and copper (ii) were found to be in the range 1.1-4.2 ohm\(^{-1}\) mol\(^{-1}\) in DMF indicating their non electrolytic nature. The values of conductance also support the structure assigned on the basis of elemental analysis. IR spectra and magnetic susceptibility values.

### CONCLUSIONS

Thus on the basis of the above studies it is concluded that the complexes posses the octahedral geometry around the central metal ion as shown in Fig. 1.

### ACKNOWLEDGEMENTS

The authors are grateful to the Principal, L.N.T, College Muzaffarpur for providing laboratory facilities. B.K. Rai is also grateful to U.G.C. for financial support for this project under Minor Research Project.
