ABSTRACT

The present work aims to report the investigation of the electrochemical behavior of 3-aryl azomethine-1,2,4-triazole derivatives in universal aqueous buffer series at mercury electrode. The electrode behavior of the studied compounds was performed via voltammetric studies, chronoamperometry, convoluted transforms, and dp polarography techniques. The relevant chemical and electrochemical parameters of 3-aryl azomethine -1,2,4-triazole derivatives were determined experimentally in universal aqueous buffer series as supporting electrolyte at mercury electrode. CPC was used for determination of the number of electrons to elucidate the mechanistic pathway of electrode reaction of aryl azomethine triazole compounds. Digital simulation method was used to confirm the accuracy of the experimental chemical parameters (homogeneous chemical rate constant) and electrochemical parameters (heterogeneous rate constant, symmetry coefficient and redox potential) via matching between the experimental and theoretical cyclic voltammograms.

Keywords: Pharmaceutical compounds, Arylazomethine, Convolution transforms, digital simulation.

INTRODUCTION

The biological activity of aryl azomethine derivatives is well known and established in the literature¹. It has been used as antitumor², anticancer³, antidiabetic⁴, antiviral agents⁵. Substituted aryl azomethine triazole have important applications in microbiology as bactericidal⁶, and fungicidal effects⁷ and pharmacological activities⁸⁹ in addition to their uses in ulcer treatment and prevention¹⁰ and antihypertensive agents to lower blood pressure¹¹. Triazoles studies are also interested in many subjects because of their synthetic characteristics and other theoretical aspects¹². Azomethine prodrugs of (R) α- methylhistamine are potent histamine H₃ receptors¹³. Azomethines not only serve as a valuable tool for pharmacological studies related to histamine H₃ receptors but also represent a promising approach to achieve therapeutic applications of histamine H₃ receptors against (R) α-methylhistamines. Several Schiff base complexes of transition metals have been synthesized and studied at different electrodes¹⁴⁻¹⁶. Azomethines have found additional uses as polymer organic frameworks (POFs) for
H₂ and CO₂ sequestering. This is a result of their large surface area. They have further been used as epoxy-derivatives for the preparation of thermostable and thermoconductive polymers. The thermal stability of the azomethines is courtesy of the rigid imine bond. Their thermal stability and thermal conductivity have been exploited for use as electrical isolators and adhesives in motors, transformers and integrated circuits.

Azomethines have been used in plastic electronics such as organic field-effect transistors, photovoltaic devices, and electrochromic devices. For example, Sek et al., synthesized a series of triphenylamine (TPA) oligomers that are normally used as hole-transporting materials in organic light emitting diodes.

Convolution transforms have been used in this work to assess the electrochemical data of 3-arylazomethine-1,2,4-triazole derivatives. The main advantage of this technique is the possibility of using all the data obtained from cyclic voltammetric experiment instead of only involving the data concerned with the peak magnitude. Convulsive transforms were found to provide high accuracy in mechanism diagnosis and rate constant determination. The inverse square root of time convolution or semi integral of the current is evaluated via the history dependent integral.

The aim of the described work here is to reports the electrochemical behaviour of some 3-arylazomethine-1,2,4-triazole derivatives, which have a biological activity, at mercury electrode in universal buffer solution via various voltammetric methods in order to give some light on the elucidation of the mechanistic pathway and determination of the heterogeneous and homogeneous parameters of the investigated compounds.

**EXPERIMENTAL**

**Chemicals**

The compounds were prepared according to the procedure reported in literature. A stock solution of 2.5 x 10⁻³ M of each arylazomethine triazole compound was prepared in ethanol. Britton – Robinson buffers in the pH range 2 – 12 were prepared. The nomenclature and structure of the investigated compounds are indicated in scheme 1.

![Scheme 1](image)

**Apparatus and techniques**

Cyclic voltammetric studies were carried out using the polarographic analyzer (from EG & G) model 264 A and HMDE (hanging mercury drop electrode) with a surface area 2.6x10⁻⁴ m², model 303A, as working electrode, Ag/AgCl as a reference electrode and Pt wire as a counter electrode. Data processing and digital simulations were performed using a software package (EG & G) Condecon-Condesim (EG & G). Coulometric measurements for calculation the number of electrons was performed using digital coulometer model 179 (from EG & G).

**Controlled potential coulometry (CPC) measurements**

The charge accumulated during the electrolysis of the compounds is given by the relation:

\[ Q = nFWM \]  \( \text{(1)} \)

Where F is the Faraday constant (96485 Coulombs/ equivalent) and the other symbols have their usual meaning.

In CPC measurements, firstly the condenser current of the inert electrolyte was measured after application of a stream of N₂ gas to the working electrode (mercury pool) then the measurements continued until the background current exhibits a
constant value of charge. Then 0.5 ml of the aryl azomethine derivatives solution (1x10^{-3} M) was introduced to the coulometry cell, the potential was selected at the top of the voltammetric peak current, and the electrolysis process was run until constancy the current. The amount of consumed charge (Q) was recorded directly from coulometer and the obtained data were given in Table 1 indicate that the cathodic reduction process consumed two electrons /depolarizer molecule.

RESULTS AND DISCUSSION

Cyclic voltammetry and convolutive voltammetry

Figure 1 indicates an example of cyclic voltammograms of the investigated aryl azomethine triazole compounds in universal B. R. buffer solution at pH 3.1 and at scan rates 200, 500 and 1000 mV.s^{-1}. It was found that the compounds under consideration exhibit one well-defined cathodic peak at scan rates ≤ 500 mV.s^{-1}, while at scan rates more than 500 mV.s^{-1} the voltammograms exhibit a small anodic peak in the reverse scan confirming a fast chemical reaction follow and coupled with electron transfer. Also, the shift of EP to more negative potential and increasing the difference between EP and EP/2 (EP-EP/2) values with scan rate confirm the sluggish of charge transfer.

It was observed that the potential of the cathodic peak (EP) varies with the logarithmic of scan rate according to the eq.(2):

\[ E_p = -1.14\left(\frac{RT}{\alpha n^a F}\right) + \left(\frac{RT}{\alpha n^a F}\right) \ln \left(\frac{k_i h}{D^{1/2}}\right) - \left(\frac{RT}{2\alpha n^a F}\right) \ln \left(\frac{\alpha n^a}{\alpha n^a}\right) \]  

Linear correlations were obtained on plotting of EP vs. log v, and the cathodic symmetry coefficients (α) were calculated from the slopes of these plots at the selected pH values. Also, the symmetry coefficients (α) were calculated from the following equation:

\[ E_p - E_{p/2} = 1.857 \left(\frac{RT}{\alpha n^a F}\right) \]  

Fig. 1. Cyclic voltammograms of the investigated aryl azomethine triazole compounds (I), (II) and (III) in B.R. buffer solution at pH 3.1 and at various scan rates
and were found to be less than 0.5 when \( n_a = 1 \) (Table 2), confirming the sluggish nature of the reduction reaction.

For irreversible charge transfer\(^{35}\), the peak current (\( i_p \)) can be related to the square root and the concentration of the depolarizers (1.25x10\(^{-4} \) M) via the following equation:

\[
i_p = 2.99 \times 10^n (\alpha n_a)^{1/2} AD^{1/2} C V^{1/2} \quad (4)
\]

At different pH values, it was noted that the investigated compounds exhibit diffusion character of the current with some adsorption contribution due to a slight deviation from the origin of \( i_p \) vs. \( E \) plot\(^{36}\). At scan rate \( \geq 1000 \text{ mV.s}^{-1} \) the heterogeneous rate constant (\( k_s \)) was computed from the voltammograms using the peak potential separation, \( \Delta E_p \), versus dimensionless parameters constants \( \psi \)^\(^{37,38} \) (Table 3).

**Table 3: Values of \( k_s \) determined experimentally and theoretically of aryl azomethine triazole compounds under consideration at 25°C.**

\( I_{\text{conv}} \) was used for determination of mass transfer coefficient of the electroactive aryl azomethine triazole compounds from Eq. (5)\(^{42} \):

\[
I_{\text{conv}} = nFAC (D)^{1/2} \quad (5)
\]

Where \( I_{\text{lm}} \) is the value of \( I \) transforms at an extreme potential past the peak, the other symbols have their known definition. The mass transfer coefficients (\( D \)) of the investigated aryl azomethine triazole compounds were computed via Eq. (5) and cited in Tables 4. The \( i_l \) vs. \( E \) plot which shown in Fig. 2 exhibits a large distance between the reductive and oxidative sweep which confirms the sluggish kinetics of the two electrons transferred. Also, the reverse sweep does not return to initial current (\( i = 0 \)) due to a fast chemical process following the electron transfer.

**Table 4: Mass transfer coefficient (\( D \)) of the aryl azomethine triazole compounds computed via different methods at 25°C.**

\*A Values determined from CV via Eq. (4), B From \( I_{\text{lim}} \) via eq. (5), and C via eq. (6). \n
The Equation used to determine the mass transfer coefficient (\( D \)) of aryl azomethine triazole compounds is the following one\(^{43,44} \):

\[
I_{\text{lim}} = i_p / 3.099(\alpha n_{\text{a}} V)^{1/2} \quad (6)
\]

**Chronoamperometry**

Chronoamperometry experiments were carried out by stepping the potential from the initial potential (-0.6 V) to final potential till -1.20
V and the current was plotted versus time. The captured chronoamperograms of 2.5×10⁻⁴ mol L⁻¹ solution of the aryl azomethine triazole compounds (I - III) were recorded at a glassy carbon electrode. Fig. 3 shows the i - t plot of aryl azomethine triazole compound (I) which reveals that the current decreases with increasing the time of the experiment.

\[ \ln k_f = -\frac{\alpha nF}{RT} (E_f - E^0) + \ln k_s \]

\( \alpha \) is the transfer coefficient, \( k_s \) is the standard rate constant. Fig. 3 shows the i - t plot of aryl azomethine triazole compound (I) which reveals that the current decreases with increasing the time of the experiment.

\[ i = nFAC\sqrt{D/\sqrt{\pi t}} \]

Where; \( i \), the current; \( n \), the number of electrons involved; \( F \), Faraday constant; \( D \), mass transfer coefficient; \( C_{\text{bulk}} \), concentration of the species in the bulk and \( t \), time. The presentation of \( i \) vs \( 1/\sqrt{t} \) exhibits linear plot and the mass transfer coefficient was determined from its slope (Table 5).

The \( k_f \) (forward rate constant) of the investigated aryl azomethine triazole compounds was calculated from equation 8,

\[ i(t) = -\beta I_1 + u \]

Where \( u = nFSC_{\text{bulk}}k(D)^{1/2} \) and \( \beta = k(D)^{1/2} \). From the slope and the intercept of \( i(t) \) vs. \( I_1 \) at \( I_1 = 0 \), the magnitude of \( k_f \) can be obtained.

The variation of the heterogeneous rate constant with the electrode potential is presented using Butler-Volmer relationship via equation (9).

\[ \text{Digital Simulation} \]

In this work, numerical simulation method was used for examining the values of the heterogeneous and homogeneous parameters determined experimentally via various electrochemical techniques as well as knowing the true nature of mechanistic pathway of the electrode reaction. In general the matching between the theoretical voltammograms with the captured one, confirm the accuracy of the determined parameters. The generated cyclic voltammograms have been performed using Condesim software Package supplied from EG & G.

In this article, the mechanistic pathway of the compounds under consideration was determined from a digital simulation for the following models: i- \( E_{\text{rev}}C_{\text{rev}} \); ii- \( E_{\text{rev}}C_{\text{im}} \); and iii- \( E_{\text{qv}}C_{\text{qv}} \) (Fig. 4). As shown the difference between the captured cyclic voltammograms (Fig. 1) and the generated models of \( C_{\text{qv}} \) mechanism (Fig. 4) confirming the validity and accuracy of the proposed mechanism.

The following are the electrochemical parameters used in simulation process:

i- mass transfer coefficient of triazole compounds (D); ii- standard electrode potential (E⁰); iii- initial concentration of the arylazomethine triazole compounds.

compounds (C mol.l\(^{-1}\)); iv- standard heterogeneous rate constant (ks, cm.s\(^{-1}\)); v- scan rate (V.s\(^{-1}\)); vi- temperature (K\(^{-1}\)); vii- homogeneous chemical rate constant (k_c s\(^{-1}\)); and the cathodic symmetry coefficient (\(\alpha_c\)).

Figure 5 exhibits well matching between the experimental voltammograms and the theoretical voltammograms of EqC\(_{irr}\) model of the aryl azomethine triazole compound (I) at pH 3.1 and a scan rate of 1000 mV.s\(^{-1}\). Table 6 shows the measured values of the experimental and theoretical electrochemical parameters which indicate the validity and the accuracy of the electrochemical parameters calculated from the experimental techniques.

The kinetic convolution I\(_2\) was used for determination of homogeneous chemical rate constant (k\(_c\)). This procedure was done via introducing different values of k\(_c\) until a value is obtained that returns I\(_2\) to zero at the end of the return sweep. A diagramatic examples of the function I\(_2\)–E plot at the true value of k\(_c\) is shown in Fig. 6. The true k\(_c\) value of the chemical step is 4.5 s\(^{-1}\) for the aryl azomethine triazole compound I at pH 3.1 (Table 6).

**Mechanistic pathway**

Controlled potential coulometry experiments revealed that the electrolysis process of the aryl azomethine triazole compounds (I, II, and III) consumed 2 electrons/molecule in acidic, neutral and alkaline solutions IR (KBr optics) spectrum of the products of electrode reaction due to saturation of the active group produce a broad band at ~ 3315 cm\(^{-1}\) (stretching) confirming the fingerprint of CH\(_2\)-NH-) group in the products. All these experimental evidence indicate that the electrode reduction pathway consumes two-electron which convert the initial active aryl azomethine triazole species to an inactive aryl azomethine triazole compounds due to the secondary amine group (CH\(_2\)-NH-).

According to above, the reduction of the investigated compounds occurs on the N=C-center in two irreversible consecutive one – electron transfer, the potential of which overlap i.e E\(^{0}\)\(_{1}\) = E\(^{0}\)\(_{2}\). It is assumed that the electron transfer is preceding by a fast proton addition then followed by another protonation i.e. H\(^+\), e\(^-\), e\(^-\), H\(^+\) which is confirmed from the shift of E\(^{0}\) with an increase in pH. Also from this behavior, it was concluded that the azomethine group is reduced in the protonated form to give anion radical in the first step and the second step is corresponding to the formation of secondary amine.

(a) Values calculated from experimental work and (b) Values calculated from theoretical work.

Fig. 6. Kinetic convolution, $i_p$, of aryl azomethine triazole (I) at pH 3.1 and sweep rate of 1000 mV.s$^{-1}$.

The obtained results indicated that the mechanism of the electrode pathway of some 3-arylazomethine-1,2,4-triazole derivatives can be summarized as follows:

\[ \text{Ar-} \text{N = CH} - \text{Ar' - OH} + \text{H}^+ \rightleftharpoons \text{Ar-} \text{N(H) - CH} - \text{Ar'-OH} \] (I)

\[ \text{Ar-} \text{N(H) - CH} - \text{Ar'-OH} \rightleftharpoons \text{Ar-} \text{N(H) - CH} - \text{Ar'-OH} \] (II)

\[ \text{Ar-} \text{N(H) - CH} - \text{Ar'-OH} \rightleftharpoons \text{Ar-CH}_2\text{NHAr'} \] (III)

\[ \text{Ar-CH}_2\text{NHAr'} \rightleftharpoons \text{Ar-CH}_2\text{NHAr'} = \text{O + H}^+ \] (IV)

As shown the mechanistic pathway of electrode reaction proceeds in the sequence $\text{H}^+$, $e^-$, $e^-$, $\text{H}^+$, i.e EEC mechanism.

CONCLUSION

The electrochemical behavior of some pharmaceutical compounds was studied in universal aqueous buffer series at mercury electrode using...
cyclic voltammetry, chronocoulometry, convolution & deconvolution transforms, and dp polarography techniques. The number of electrons participating in electrode reaction was determined for elucidation of the mechanistic electrode pathway. Digital simulation method was used to confirm the nature of electrode reaction and the accuracy of the experimental chemical and electrochemical parameters via matching between the experimental and theoretical cyclic voltammograms.
