ABSTRACT

KDML 105 is the famous fragrant rice of Thailand. 2AP acts as the characteristic compounds in fragrant-rice cultivars. 2AP accumulation has been reported in relationship with proline content and the growth rate of rice. Several factors have been reported to affect the poline and 2AP contents. We determined the combinatorial effect of gamma irradiation and salt concentration on the 2AP and proline contents of 5 day-old KDML 105 rice-seedling. In the growth condition under 20 mM of NaCl concentration the proline content of gamma irradiated rice increased compared to the gamma irradiated rice treated without 20 mM of NaCl concentration. While, the shoot-length of 5 day-old gamma irradiated rice-seedlings under 20mM NaCl concentration cannot be observed when compared to gamma irradiated rice-seedling without salt concentration. The 2AP content of gamma irradiated rice-seedlings under 20 mM of NaCl concentration had approximately 2.6 to 3.1 times higher than in the growth condition without salt concentration of gamma irradiated rice-seedlings. Our results indicate that the combination of gamma irradiation technique and salt concentration can be used for improving the 2AP content in rice.

Keywords: Gamma irradiation, Salt stress, 2-acetyl-1-pyrroline, Proline content, KDML 105.

INTRODUCTION

The relationship between 2AP and proline contents of rice have been reported by many researchers. In the biosynthesis of 2AP, proline acts as the first precursory molecules. The researchers have reported that the accumulation of proline in rice may affect the accumulation of 2AP. Suprasanna
et al., found that when proline in callus of Basmati rice increased, the 2AP content also increased. The 2AP content also increased along with increasing of proline content in the callus and rice seedling of KDML105 rice. Poonlaphdecha et al., also reported the increase of 2AP accumulation in rice under salt treatment due to the increase of proline content. Moreover the 2AP content was related to the proline content when rice was treated with the reducing of solar intensity. On the contrary, Sansenya et al., reported the 2AP accumulation in rice grain were not correlated with proline accumulation in rice grain of Thai local rice.

In recent years, many researchers have reported the effect of salt concentration on the 2AP accumulation in rice. The increase of salinity may affect the increase of 2AP content in grain of aroma rice variety. Poonlaphdecha et al., reported that under salt treatment the increasing of 2AP content was obtained in rice grain but the salt concentration did not affect the other related compounds in the biochemical 2AP synthesis pathway such as GABA.

Gamma irradiation is the technique useful for inducing mutation to biological compounds of plant. In rice gamma irradiation has affected rice growth depending on gamma dose. Low gamma doses stimulated the rice growth, whereas at high gamma doses the inhibition of rice growth was observed. Gamma irradiation also affects the biological compounds of rice. Hwang et al., found that the gamma irradiation caused some micronutrient content such as tocopherol in rice mutant line higher than in the control rice. Sansenya et al., reported that the gamma irradiation affected the related biological compounds in 2AP biosynthesis pathway. According to the results, the gamma irradiation caused decrease of the GABA content, while the increasing of 2AP content was observed in Thai upland rice.

In this study, we report the combined effect of salt concentration and gamma irradiation to the rice growth and the related biological compounds in 2AP biosynthesis pathway such as proline and 2AP of KDML105 rice.

EXPERIMENTAL

Plant material and growth condition

Seed of KDML 105 was obtained from the rice field in Roi-Et province, Thailand. The rice sample was sterilized with 0.1% NaClO and then washed with deionized water. The sterilized rice seeds was then roasted in hot air to decreased the moisture content to <13%.

For gamma irradiation, 100 g were packed with polyethylene bag and then irradiated with the gamma ray intensity of 0 (control; without gamma irradiation), 20, 40, 60, 80, 100, 150, 300, and 500 Gy. We used 137Cs as the gamma source with the dose rate of 3 Gy/min at room temperature. The gamma irradiation was provided by Gamma Irradiation Service and Nuclear Technology Research Center, Faculty of Science, Kasetsart University, Thailand.

Effect of germination time on proline content of non-gamma irradiated rice seedling

Fifty grams of non-gamma irradiated rice seeds were soaked in 100 mL of deionized water for 24 h. The rice seeds germinated on the germinating paper moistened by deionized water. The germination experiment was incubated at ambient temperature with 0 (without germination time), 1, 2, 3, 4, and 5 days for germination time, and during seed germination the experiments were sprayed with deionized water every 12 h. The germination seeds were harvested at the end of germination time at 0 h, 24 h (1 day), 48 h (2 days), 72 h (3 days), 96 h (4 days) and 120 h (5 days). Then the samples were kept at -20°C until proline quantified.

Effect of salt concentration on proline content and growth of non-gamma irradiated rice seedlings (5 days old)

Fifty grams of non-gamma irradiated rice-seed were soaked in 100mL-salt solution of 0 (without NaCl concentration), 20, 40, 60, 80 and 100mM of NaCl concentration for 24 h. The germination experiments were provided at the germination time that produced highest proline content (5 days). During of duration germination, the germination experiments were sprayed with salt solution of the same concentration as a soaking solution for every 12 h until 5 days. Next, sample processing was the same as experiment above.
Effects of gamma irradiation and salt concentration on 2AP content, proline content of rice seedling (5 days old)

For the experiment without salt condition, the non-gamma irradiated rice-seed and gamma irradiated rice-seed were soaked in 100 mL of deionized water for 24 h. Then, the germination experiments were sprayed with deionized water for every 12 h until 5 days.

For the experiment with salt condition, the non-gamma irradiated rice seed and gamma irradiated rice-seed were soaked in 20 mM salt solution for 24 h. Then, the germination experiments were sprayed with 20 mM salt solution for every 12 h until 5 days.

The rice-seedlings (5 days old) in both experiments were harvested and kept at -20°C until 2AP and proline quantified.

Effects of gamma irradiation and salt concentration on plant growth of rice-seedlings (5 days old)

For effect of salt concentration on plant growth. One hundred of non-gamma irradiated rice-seeds were soaked in salt solution including 0 (without NaCl concentration), 20, 40, 60, 80 and 100 mM for 24 h. The germination experiments were carried out at the ambient temperature and sprayed with salt at the same concentration as soaking solution for every 12 h until 5 days. The rice seedlings at 5 days old were harvested and the rice shoot-lengths were measured.

For the effect of gamma irradiation on plant growth one hundred of non-gamma irradiated rice-seeds and gamma irradiated rice-seeds were soaked in deionized water for 24 h. During duration germination, the experiment were sprayed with deionized water every 12 h until 5 days. Then, the rice-seedlings (5 days old) were harvested and the rice shoot lengths were measured.

Proline quantification

Proline content of germinated rice was determined by the method of Sansenya et al.,8. Rice samples of germinated rice-seeds were homogenized with CryoMill (Retch, Germany) by using liquid nitrogen. For proline determination, 0.3 g of homogenized rice samples were extracted with 3% sulfosalicylic acid and before proline reaction the extraction solution were filtered with Syringe Filter (0.45 μm). The filtered solution for proline reaction was mixed with 3 mL of ninhydrin solution and 2 mL of glacial acetic acid, then the mixed reaction solution were boiled for 20 min. After boiling, the reaction solution were extracted with 4 mL of toluene. Next, the extracted solution was spectrophotometric at 520 nm. The proline concentration was calculated with the standard curve of proline: $y = 0.413x - 0.014$ ($R^2 = 0.999$).

2AP quantification

The 2AP content of rice samples were determined by the modified method of Sansenya et al.,8. The homogenized rice samples for 2AP quantification was provided in the same way as in experiment for proline quantification. An agilent GC-MS (Agilent 7890A GC-7000 Mass Triple Quad) was used for the analysis. A 4 μL portion of the extract was injected into a DB-Wax (60 m × 0.25 mm i.d. × 0.25 μm film thickness) fused silica capillary column (J&W Scientific, Folsom, CA). The injector was set at 240°C, and split mode was applied with a split ratio of 5:1. Helium gas was used as the carrier gas with a constant flow rate of 1.5 mL/min. The column oven was operated via temperature program: column temperature was isothermally maintained at 40°C for 2 min programmed at a rate of 10°C/min to 100°C, then at a rate of 5°C/min to 150°C and then at a rate of 30°C/min to 250°C; the column temperature was then maintained isothermally at 250°C for 15 min. The mass spectrometer was used in the electron ionization mode. The ion source temperature was set at 230°C and ionization energy was set at 70 eV. Multi reaction monitoring (MRM) mode was set up to analyze 2AP. The precursor ion m/z 111 and the product ion m/z 83 were selected for 2AP with collision energy of 5 V. The mass spectrometer detection dwell time was 30 ms. Under these conditions the retention times of 2AP were found to be 18.92 min. Quantification of 2AP was performed by measuring the area of ions at m/z 83, and the amounts of 2AP were calculated from its calibration curve, $y = 19.68x - 7.56$, ($R^2 = 0.997$).
Statistic analysis

All the samples were expressed as the means ± standard deviation (means ± SD). The statistical significance of differences among experimental groups was evaluated by one-way analysis of variance (ANOVA). When the ANOVA revealed significant between-group differences a post hoc analysis was performed using Duncan’s multiple-range test comparisons. The significance level was set at $P < 0.05$.

RESULTS AND DISCUSSION

Effect of salt concentration on proline content and growth of 5-day-old rice-seedling

Our results show that the proline accumulation of rice was determined during duration of rice germination. The significant increase of proline content was observed at 1 day of duration germination compared with non-germinated rice (0 day). The proline content still increased after 1 day to 5 days during duration of germination (Table 1). In duration of seed germination the soluble protein is degraded to the free amino acid by proteolytic enzyme\(^ {18}\). The proline is one of amino acid that is related to plant growth and plant differentiation\(^ {19}\).

Our results were also performed according to the previous report, the proline content of 5-day-old rice-seedlings was 9.5 times compared to that of non-germinated rice seed (0 day).

Many researchers reported that the proline was one of the amino acids that respond to the environmental stress such as salt stress, dough stress and radiation stress\(^ {20-26}\). Our result shows the correlation of proline accumulation and plant growth of 5 days old rice-seedlings under salt condition. Rice-seedlings (5 days old) under salt condition reveal that the proline content increased at low salt-concentrations (20 and 40mM NaCl concentration) (Fig. 1). The highest proline content of 5 days old rice-seedlings was observed at 20 mM NaCl concentration and approximately 2 times compared to 5 days old rice seedling without salt concentration (0mM NaCl concentration). The significant decreasing of proline content was observed when rice was treated with high salt-concentration and approximately 3.4 times decreasing, compared with highest proline content of 5-day-old rice-seedlings treated with 20mM salt concentration.

The correlation of proline content and rice-shoot-lengths of 5 days old rice-seedlings was found in all salt conditions. The increasing of rice shoot-lengths was observed when the proline content increased. While, the low concentration of proline content was obtained from shorter rice shoot-lengths. Moreover the results show that we may obtain highest proline content and highest rice

![Fig.1](image-url)
shoot-lengths from low salt-concentrations (20 mM salt concentration). The rice shoot-lengths and proline content were decreased after rice was treated with high salt-concentrations (Fig. 1 and 2). This results agree with Kibria et al. the proline content significantly increased in BRRI dhan rice cultivar under low salt concentration (20 and 40 mM salt concentration), while at above 60M salt concentration it caused decrease in the proline content of rice. For other rice cultivars the high salt concentration caused increasing the proline content of rice such as BRRI dhan Binadhan-8 and Binadhan-1027. Our result and other report indicate that in different rice cultivars the level of salt tolerance might be different and the maintenance of proline content should also be different.

The 5 days old rice seedlings show increase of rice shoot-length under 20mM NaCl concentration compared to rice shoot-lengths of control rice and 40 to 100 mM NaCl concentration](image)

**Effect of salt concentration on the proline content and growth of 5 days old gamma irradiated rice-seedlings**

Gamma ray has an effect on living cells of organism depending on the gamma dose. The gamma ray has generated free radical and this induced mutation in plant cells. We determined the effect of gamma irradiation on the proline content and the plant growth of 5 days old rice seedlings with and without salt concentration (20mM NaCl). Proline content of gamma irradiated rice-seedlings with and without 20 mM NaCl increased after treating with 40 and 60 Gy with respect to 0 Gy. At high gamma doses (80 to 500 Gy) the proline content decreased continuously in both conditions (with and without 20mM NaCl concentration) (Fig. 3A). The largest decrease of proline content of gamma irradiated rice seedlings were observed in case of without 20mM NaCl, whereas the slight decrease of proline content was observed in gamma irradiated rice-seedlings treated with 20 mM NaCl. The highest and the lowest proline contents of gamma irradiated rice-seedlings in both conditions were obtained from 20 Gy for highest proline content and 500 Gy for lowest proline content respectively. The trend of proline content of gamma irradiated rice-seedlings with 20mM NaCl had higher proline content of gamma irradiated rice-seedlings than in case of without 20mM NaCl of all gamma dose. Gamma ray also affects the shoot length of rice-seedlings in rice seedlings. Compared with the control, the gamma irradiated rice-seedlings treated without 20mM NaCl concentration at 20 Gy to 150 Gy showed significant differences in their shoot lengths. The highest shoot lengths were observed at 20Gy gamma dose (Fig. 3 B; gray bar and Fig. 4). While, their shoot lengths were lower in the 300 Gy and 500 Gy gamma irradiated rice-seedlings than in the control rice (Fig. 3 B; gray bar and Fig. 4). Interestingly, for the gamma irradiated rice-seeds treated with 20mM NaCl concentration, the germination can be observed in duration of 3 days, but the transformation from germinated rice-seeds to rice-seedlings cannot be observed in case of gamma irradiation at 20 Gy to 500 Gy with respect to the control set (Fig. 3 B; dark gray bar and Fig. 5). The stimulation via low gamma-irradiation dose under salt condition to increased proline content of rice-seedlings in rice seedlings of our results are similar to the study of El-Beltagi et al., who found that all salt concentrations under 50Gy gamma dose induced the proline content in the shoots of Cowpea plants. Many reports show that salt condition affects the proline level in plants cell. In general, proline has many behaviors during salt stress such as accumulation of energy reservoir, nitrogen source, water storage, pH stability in the cell and hydroxyl radical scavenging. Gamma rays may also induce the proline content under low gamma dose described by Al-Enezi and Al-Khayri. Gamma irradiation produces the radical having many effects on plant cells. The increase of proline content of gamma irradiated rice-seedlings under salt condition compared to the gamma irradiated rice seedlings treated without salt concentration may affect plant growth under combination stress (Fig. 3A). At low gamma doses (20 Gy to 150 Gy) the shoot lengths of 5 days old rice-seedlings are higher than those of control rice (Fig. 3B gray bar). However, high gamma doses (300Gy to 500 Gy) seem to inhibit the plant growth of 5 days old rice seedlings (Fig. 3B; gray bar and Fig. 4). Many researchers have been reported the stimulation of plant growth by low doses of gamma-irradiation. Chandrashekar et al. reported the higher shoot lengths of Terminalia arjuna Roxb than the control set under low doses of gamma-irradiation. Sansenya et al. also reported the stimulation of low gamma...
irradiation doses on shoot lengths of Thai black glutinous rice. Moreover, under combination stress (salt concentration and gamma irradiation) it inhibited plant growth of 5 days old rice seedling of all gamma doses with respect to the control rice (Fig. 3B dark gray bar and Fig. 5). Previous researchers also reported the inhibition of growth of gamma irradiated plants under salt condition. The shoot lengths of gamma irradiated Tarrom Hashemi \((Oryza sativa L.)\) had decreased under salt condition. More, the decreasing of germination percentage were also observed in gamma irradiated rice-seeds under salt condition \((Tarrom Hashemi)\)\textsuperscript{21}. The inhibition of growth of gamma irradiated plants under salt condition may cause many damages in the genome of plant\textsuperscript{39}. Moreover, while plant growth under salt condition had effect on the loss of water content from plant and inducing toxicity in the plant cell may cause inhibition of the growth rate of plant\textsuperscript{40}.

**Effect of salt concentration on 2AP content of 5 days old gamma irradiated rice seedlings**

2AP is the aroma compounds that acts as a characteristic compound for fragrant rice\textsuperscript{2,8,41,42}. This compound is synthesized via L-proline metabolism and is associated with inactive betaine aldehyde dehydrogenase (Badh2)\textsuperscript{2}. The level of 2AP accumulation in rice may be caused by several environmental factors such as salt stress, dough stress, reducing of solar intensity and gamma irradiation\textsuperscript{6,7,14,15,43}. Our results show that the gamma irradiation affects increasing of 2AP content of 5 days old rice seedlings of all gamma dose compared with control rice (Fig. 6 gray bar). The 2AP content of gamma-irradiated rice increases when gamma dose increases (20 Gy to 300 Gy), whereas at 500 Gy the 2AP content of gamma irradiated rice decreased with respect to other gamma doses (20 Gy to 300 Gy) (Fig. 6 gray bar). We have determined the effect of salt concentration on 2AP content of 5 days old
gamma irradiated rice-seedling. The 2AP content of non-gamma-irradiated rice (0 Gy) that grew under 20mM NaCl concentration had 6.7-fold higher than in case of non-gamma-irradiated rice (0 Gy) treated without 20mM NaCl concentration (Fig. 6). While other 5 days old rice seedlings treated with 20Gy to 500Gy with 20mM NaCl concentration also had 2AP content approximately 2.6 to 3.1-times higher than in case of gamma irradiated rice seedling without 20mM NaCl concentration. Moreover the 2AP content of 5 days old rice seedlings treated with gamma irradiation and with 20mM NaCl concentration gradually increased at 20 Gy to 80 Gy, whereas the 2AP content continuously decreased at 100 Gy to 500 Gy compared to control rice (Fig. 6 dark gray bar). Salt and gamma irradiation condition have been regarded as factors that affect the 2AP accumulation in rice. The increase of 2AP content under salt concentration has been reported by Poonladpdecor et al.,6 and Yoshishashi et al.,43. The gamma irradiation also affected the increasing of the 2AP content in germinated rice and gamma irradiated rice-seeds14,15. Proline is the precursor for 2AP synthesis metabolism, under saltcondition it has been reported to stimulate the proline content in rice. Increases of proline content in gamma irradiated rice were also reported34. Fig. 3A of our result also shows that the proline content of gamma irradiated rice-seedlings with 20mM salt concentration condition has increased with respect to controlled rice. The increase of proline content under combination factors might explain the increasing of 2AP content of gamma-irradiated rice under 20mM NaCl concentration.

CONCLUSION

Proline content of KDML 105 rice gradually increased from 1 to 5 days compared to non-germinated rice during germination. The proline content and the shoot-length of 5 days old rice-seedlings had highest value for 20mM NaCl concentration, whereas high salt concentration seemed to inhibit proline content and rice shoot-length. The proline content of 5 days old gamma irradiated rice-seedlings under 20mM NaCl concentration had higher value than that of gamma-irradiated rice treated without salt concentration. Salt concentration has inhibited the rice shoot-lengths of gamma-irradiated rice compared to the gamma-irradiated rice growth in the condition of without salt concentration. In growth condition with 20mM NaCl concentration, the gamma irradiated rice-seedling had the 2AP content higher than in case of no salt concentration.

ACKNOWLEDGMENT

This research was supported by the National Research Council of Thailand (Grant 2560A16502109) and Rajamangala University of Technology Thanyaburi. We are also grateful to Kadsada Sala for providing plant samples.
