ABSTRACT

Oxidation of secondary alcohols is an important part of synthetic organic chemistry. Various studies are carried out at different reaction conditions to determine the best mechanistic pathways. In our study, oxidation of different secondary alcohols was done by using Benzimidazolium Fluorochromate in dimethyl sulphoxide, which is a non-aqueous solvent. Oxidation resulted in the formation of ketonic compounds. The reaction showed first order kinetics both in BIFC and in the alcohols. Hydrogen ions were used to catalyze the reaction. We selected four different temperatures to carry out our study. The correlation within the activation parameters like enthalpies and entropies was in accordance with the Exner’s criterion. The deuterated benzhydrol (PhCDOHPh) oxidation exhibited an important primary kinetic isotopic effect ($k_H/k_D = 5.76$) at 298 K. The solvent effect was studied using the multiparametric equations of Taft and Swain. There was no effect of addition of acrylonitrile on the oxidation rate. The mechanism involved sigmatropic rearrangement with the transfer of hydrogen ion taking place from alcohol to the oxidant via a cyclic chromate ester formation.

Keywords: Benzimidazolium fluorochromate, Chemical kinetics, Oxidation, Reaction mechanism, Kinetic isotope effects, Correlation analysis, Alcohols, ketones.

INTRODUCTION

Organic reaction mechanism not only deals with the relationship between the molecular structure and chemical properties but tells us about the rate constants. Thus, the organic reaction mechanism is a multidisciplinary one which involves organic chemistry, physical chemistry and if some metal compound is involved also inorganic chemistry. Correlation analysis of structure and reactivity is of great importance as nature of the substituent can cause field effect, steric effect or resonance, which directly affects reaction rates in the redox process. It also gives us information about the reaction mechanism, transition state, nature of the intermediates, oxidizing and reducing species formed during the course of a chemical reaction.

Chromium (V1) is a versatile oxidant which is usually found in the chromic acid, metal dichromates and metal halo chromates. It is normally soluble in water and insoluble in most of the organic solvents. Many chromium oxidants have been used in both aqueous and non-aqueous media for the
study of oxidation of various organic compounds. Cr (VI) reagents are known to be multifunctional and can oxidize almost all the organic functional groups. Many chromium complexes have been prepared and used in the synthetic organic chemistry. Oxidation of secondary alcohols to the carbonyl compounds by the oxidants containing chromium (VI), has been widely studied. BIFC is also a very mild and selective oxidizing agent. Most of the oxidation by BIFC has been carried out in an aqueous medium. In this paper we report the oxidation of different secondary alcohols by BIFC in non-aqueous medium. We feel our study on correlation analysis of different reactions will not only establish mechanism of the reaction but also determine kinetic parameters of the reaction, nature of reactive species and effect of solvent. The literature survey has also revealed that the oxidation of secondary alcohols by BIFC in the non-aqueous medium has not been done and presented so far thus we have used dimethyl sulphoxide as a solvent for our study. The main purpose of our research was to study rate constants, the effects of solvent for oxidative surfaces and propose an appropriate mechanism for oxidation.

EXPERIMENTAL

Materials
All the substrates (alcohols) taken were the commercial products of fluka. Anhydrous magnesium sulfate was used to dry the liquid alcohols, which were then subjected to fractional distillation. Diphenyl methanol was purified by recrystallizing from ethyl alcohol. BIFC was prepared by the reported method. Iodometric titration was used to check its purity. Deuterated benzhydrol (PhCDOHPh) was prepared by the method available in the literature. NMR spectra confirmed its purity of 96 ± 5%. We have used P-toluene sulphonlic acid (TsOH) as a hydrogen ions source. Purification of solvents was done by the methods available in the literature.

Product Analysis
We have taken 0.1 mol secondary alcohols and 0.01 mol of BIFC and prepared its 100 mL solution using DMSO solvent. 0.5 mol dm$^{-3}$ of P-toluene sulphonlic acid (PTS) was also added for the supply of H$^+$ to prevent photo-oxidation. Above mixture was covered with a black paper and placed in the dark place for a day, till the reaction was complete. Then non-aqueous layer was separated, rinsed with H$_2$O and was dehydrated using anhydrous magnesium sulphate. The yields of the products were approximately 87%. The chromium oxidation state was found to be 3.92 ± 0.14, in entirely reduced reaction mixture, which was ascertained by the iodometric titration method.

Kinetic measurement
For our experiments we used pseudo-first-order conditions, for which we took excess of alcohol over BIFC. DMSO was used as solvent, if other than specified.

All the studies were done at a constant temperature (± 0.1 K), and up to the 80% of reaction was observed by observing the decrease in the concentration of BIFC spectrophotometrically at a wavelength of 364 nm. Linear least squares method was used for the calculations of pseudo-first-order rate constant and a graph between log [BIFC] versus time was plotted. The reactions were repeated and it was observed that the rate constants were consistent with in ±3% limit.

RESULTS
Oxidation of secondary alcohols by BIFC resulted in the production of ketones. In general, overall reaction can be expressed as shown in the eqn. 1 (where BI = benzimidazolium). BIFC undergoes a 2-electron transformation which is clear from the below equation.

\[ R_2CHOH + O_2CrFO-BIH^+ \rightarrow R'_2C=O + H_2O + CrOFO^- - BIH^+ \]  

Rate law
The reaction order was found to be first with respect to BIFC. Fig. (1) illustrates a typical kinetic run & Fig. (2) represents order of reaction.
Moreover, the rate constant was independent of the initial concentration of BIFC. The reaction rate increased directly with the increasing concentration of the alcohols\textsuperscript{20} (Table 1). The plot of $1/k_{obs}$ versus $1/[alcohol]$ plot was linear with the slop on the rate ordinate\textsuperscript{23} suggesting the Michaelis-Menten type of kinetics with respect to the alcohols (Fig. 3). This is represented by the Eqn. (2). Equation (3) is referred to the mechanism and Eqn. (4) assigns the rate law.

$$\text{Sec. Alcohol} + \text{BIFC} \rightarrow \text{[Cyclic chromate ester complex]} \rightarrow \text{Product} \tag{2}$$

$$\text{Rate} = k_j [\text{Sec. Alcohol}] \times [\text{BIFC}] / (1 + K [\text{Sec. Alcohol}]) \tag{3}$$

**Induced polymerization test of acrylonitrile**

In the nitrogen atmosphere, the alcohols oxidation was ineffective to induce the acrylonitrile polymerization\textsuperscript{19}. Moreover, there was no effect of addition of acrylonitrile on the oxidation rate. This clearly indicates that no free radical formation is observed during reaction. (Table 1).

*Contained 0.001 mol dm\textsuperscript{-3} acrylonitrile

\textsuperscript{*} PTS was used for the supply of H\textsuperscript{+} needed to increase the rate of the reaction. The rate of secondary alcohols oxidation was increased with the increase in the (H\textsuperscript{+}) acidity as shown in the (Table 2) and Fig. (4). The dependence of hydrogen ions can be represented by the following equation.

$$k_{obs} = a + b [H\textsuperscript{+}]$$

### Kinetic isotope effect

Primary kinetic isotopic effect\textsuperscript{24,25} was exhibited by the deuterated benzhydrol
(PhCDOHPh) and $k_H/k_D$ value of 5.76 was obtained at a temperature of 298 K\textsuperscript{20,21}. A significant initial kinetic isotopic effect was demonstrated by the PhCDOHPh oxidation. This confirmed the fact that the cleavage of α-C-H bonds is taking place in the rate-determination step\textsuperscript{26}. A significant initial kinetic isotopic effect was demonstrated by the PhCDOHPh oxidation (Table 3).

**Influence of temperature on the reaction rate**

The kinetic study of ten secondary alcohols oxidation has been done at different temperatures viz. 318, 308, 298 and 288K in DMSO solvent and the calculations of activation parameters has been done (Table 3). The log $k_2$ at different temperatures was linearly related\textsuperscript{20,21} to 1/T in all the alcohols as shown in the (Fig. 5), which verifies the Arrhenius equation\textsuperscript{27} for these oxidations.

**Influence of solvents**

Oxidation of different secondary alcohols was studied in different organic solvents\textsuperscript{28}. We have used many organic solvents as listed in the Table (4). Due to the solubility\textsuperscript{20,21} of BIFC and its reaction with alcohols the solvents choice was restricted\textsuperscript{19}. There was no reaction found with the selected solvent. The kinetics\textsuperscript{19} of all solvents was similar. Therefore, we have taken 2-hydroxy propane as the representative secondary alcohol. The value $k_2$ at 308 K is listed in Table 4. (cf. Figure 6).
DISCUSSION

The correlation within the activation parameters like enthalpies and entropies of the ten secondary alcohols oxidation was not satisfactory \((r^2 = 0.9391)\), indicating that the compensation effect was not operative in this reaction. The correlativity was in accordance with the Exner's criterion. An Exner's graph was plotted between log \(k_2\) at two different temperatures 298 K and at 318 K. The graph was linear and \((r^2)\) value was 0.9989 (Fig. 7). The isokinetic temperature has the value 717 ± 84 K, which was evaluated by using the Exner's plot. The isokinetic relationship was determined and it suggested that all the secondary alcohols are oxidized by the same mechanism and the change in the reaction rate was controlled by both the changes in the enthalpy and entropy of the activation.

The oxidation rate constants, \(k_2\) in all the solvents used were correlated in the term of linear solvation energy relationship (LSER) of Kamlet and Taft.\(^{33}\)

\[
\log k_2 = A_0 + p\pi^* + b\beta + a\alpha \tag{5}
\]

In this equation, \(\pi^*\) represented the solvent polarity, \(\beta\) the hydrogen bond acceptor basicity, and \(\alpha\) is the hydrogen bond donor acidity. \(A_0\) is the intercept as per the standard line equation. It can be stated here that 12 out of 18 solvents had zero value for \(\alpha\). The correlation analysis results with respect to Eqn. (5), a parametric equation involving \(\pi^*\) and \(\beta\), and separately with \(\pi^*\) and \(\beta\) are given below as equations (6)-(9).

\[
\begin{align*}
\log k_2 &= 1.52(±0.12)\pi^* + 0.11(± 0.11) \beta + 0.26(±0.09) \alpha -3.92 \tag{6} \\
R^2 &= 0.8876; \text{sd} = 0.16; n = 18; \psi = 0.32 \\
\log k_2 &= 1.53(±0.11)\pi^* + 0.10(± 0.10) \beta - 3.93 \tag{7} \\
R^2 &= 0.8874; \text{sd} = 0.15; n = 18; \psi = 0.31 \\
\log k_2 &= 1.57(±0.11)\pi^* - 3.99 \tag{8} \\
R^2 &= 0.8763; \text{sd} = 0.16; n = 18; \psi = 0.39 \\
\log k_2 &= 0.32(± 0.23) \beta - 2.92 \tag{9} \\
R^2 &= 0.0902; \text{sd} = 0.39; n = 18; \psi = 1.03
\end{align*}
\]

Here \(n\) is the number of data points and \(\psi\) is the Exner's statistical parameter.

However, the correlation was not satisfactory by Exner's criterion (cf. eqn. 6). The main contribution was due to polarity of the solvent. It singly accounted for ca. 85% of the data. Both \(\beta\) and \(\alpha\) played relatively minor roles. Solvent effect data were analyzed in relation to Swain's equation, which included the cation and anion solvating conception of the solvent.

\[
\log k_2 = aA + bB + cC \tag{10}
\]

Where \(A\) denotes the anion-solvating power of the solvent and \(B\) denotes the cation-solvating power, \(C\) denotes the intercept term and \((A+B)\) indicates the polarity of solvent. The rate was determined in different solvents in terms of eqn. (10), by using \(A\) and \(B\) separately with \((A+B)\).

\[
\begin{align*}
\log k_2 &= 0.53 ± (0.02)A + 1.68( ± 0.02)B -5.83 \tag{11} \\
R^2 &= 0.9981; \text{sd} = 0.01; n = 19; \psi = 0.03 \\
\log k_2 &= 0.21 ± (0.51)A - 4.79 \tag{12} \\
R^2 &= 0.0059; \text{sd} = 0.42; n = 19; \psi = 1.06 \\
\log k_2 &= 1.60(± 0.08)B -5.69 \tag{13} \\
R^2 &= 0.9791; \text{sd} = 0.07; n = 19; \psi = 0.19
\end{align*}
\]
The rate of oxidation of 2-propanol and other secondary alcohols in different solvents showed excellent correlativity in terms of Swain's equation (cf. eqn. 11), which plays a major role with cation solvating strength. In fact, cation solvating power accounts for 99% of the data. The correlativity with the anion solvating power was minimal. The solvent polarity indicated by (A + B), was also considered for 89% of the data.

**Correlation analysis of reactivity**

The rate of alcohols oxidation failed to give any important correlation separately with Taft's $\sigma^*$ and $E_s$ values. There was no significant co-linearity ($r^2 = 0.2332$) between $\sigma^*$ and $E_s$ of the 8 substituents.

\[
\log k_2 = -1.76(\pm 0.16) \sum \sigma^* - 2.14 \\
\text{r}^2 = 0.9509; \ sd = 0.19; \ n = 8; \ \psi = 0.22; \ T = 298 \text{ K}
\]

\[
\log k_2 = -1.34(\pm 0.99) \sum E_s - 2.82 \\
\text{r}^2 = 0.2324; \ sd = 0.76; \ n = 8; \ \psi = 0.92; \ T = 298 \text{ K}
\]

Therefore, the rates were correlated in terms of Pavelich-Taft's dual substituent-parameter equation (17).

\[
\log k = p^* \sum \sigma^* + \delta \sum E_s + \log k_0
\]

The correlativity was excellent as the reaction constants were negative as shown in the (Table 4). This supports the fact that in the intermediate state of the rate determination step, there is a carbon center with the electron deficiency. This negative steric hindrance indicated a steric acceleration of the reaction. It can be described as based on the high ground state energy of highly crowded alcohol. The rapid oxidation of 1-phenyl ethanol and benzhydrol happened due to the stabilization of the carbon centre with electron-deficiency in the transition state by the phenyl group by resonance.

**Mechanism**

In the present study due to the presence of considerable primary kinetic isotope effect ($k_H/k_D = 5.76$) at 298 K, it was confirmed that the cleavage of α-C-H bond was taking place in the rate-determining step. The negative value of reaction constant and the considerable deuterium isotope effect both are indicative of the presence of an electron-deficient carbon centre in the transition state. Therefore, the transfer of hydride-ion from secondary alcohol to the BIFC is suggested. The bigger role of cation-solvating power of the solvents also supports the hydride ion transfer mechanism. The hydride ion transfer can occur either via an acyclic bimolecular reaction or may occur due to the involvement of a cyclic, planner and symmetrical transition state of chromate ester. The reaction is a two-step process, which was duly supported by the kinetic studies. Therefore, the whole mechanism is suggested to involve formation of the cyclic chromate ester formation in the rapid first phase. The slower second phase involves decomposition of the cyclic ester unit via a cyclic concerted symmetrical transition state via sigmatropic rearrangement leading to the formation of the product as represented above. The polar transition state is also supported by the observed negative value of entropy of activation. The solvent effect has also indicated that the intermediate state is more polarized than the reactant. Finally, we can say that BIFC is a very effective, mild oxidant, which can be used for the synthesis of ketonic compounds.

**ACKNOWLEDGEMENT**

We are thankful to our HOD, Professor Kailash Daga, for providing laboratory facilities and chemicals needed for the conduct of this work, executed at the department of Chemistry, Jai Narain Vyas University, Jodhpur, India.
