ABSTRACT

In this research, we have studied the structural properties of phospholipids, surrounding single-walled carbon nanotube (SWCNT, by using ab-inition and molecular dynamics simulation. Carbon nanotubes (SWCNTs) are very common in medical research and are being highly studied in the fields of biosensing methods for disease treatment and efficient drug delivery and health monitoring. The transportation of SWCNT through the cell membrane widely investigated because of many advantages. Because of the differences among force fields, the energy of a molecule calculated using two different force fields will not be the same. In this study difference in force field illustrated by comparing the energy of calculated using force fields, MM+, Amber and OPLS. The quantum Mechanics (QM) calculations were carried out with the GAUSSIAN 09 program based on density functional theory (DFT) at B1LYP/6-31G* level. In our recent study the electronic structure of open-end of SWCNT and transportation of SWCNT through the phospholipids in skin cell membrane have been discussed for both vacuum and solvent media.

Key words: Solvent effect, Phospholipids membrane, Single walled carbon nanotube.

INTRODUCTION

Nature provides us with a very large number of channels or nano-pores embedded in cell membranes. The function of channels is to allow selectivity and specificity for a variety of molecular species transport across the cell membrane. These channels, included: a) ligand-gated channels, b) voltage-gated channels, c) Second messenger gated channels, d) mechanic sensitive channels. Gap junctions: porins not gated1-7.

The discovery of carbon nanotubes (CNT) in 1991 heralded the era of nanoscience and nanotechnology8-11.

Nanotubes of carbon and other materials, due to their electronic, optical and mechanical properties find applications in several fields12-18.

The space available inside the nanotube enables it to match phospholipids outside. This makes the carbon nanotube an ideal medium for storing high energy materials19-21.
Carbon nanotubes (CNTs) since their discovery\textsuperscript{22} have been the focus of scientific research due to their outstanding chemical, mechanical and electrical properties. Single walled carbon nanotubes (SWCNTs) are of particular interest because of their size and superior electrical properties\textsuperscript{23}. SWCNTs have been used to realize many molecular scale electronic devices\textsuperscript{24-29}.

Membranes are asymmetric structures. The choline-containing phospholipids are located mainly in the outer molecular layer. This asymmetric distribution is maintained by an ATP-dependent protein which specifically trans-locates phosphatidyl-ethanolamine (and phosphatidyl-serine) to the inside of the plasma membrane\textsuperscript{30-33}. All major lipids in membranes contain both hydrophobic and hydrophilic regions and are therefore termed amphipathic. Dipalmitoylphosphatidylcholine (DPPC) and dimyristoylphosphatidylcholine (DMPC) are taken as phospholipids with equal polar heads and with the difference in the length of hydrocarbon chains\textsuperscript{34,35}. These two molecules have saturated fatty acid tail groups\textsuperscript{36-39}.

On a molecular level it has been of interest to explore to what extent PC head groups differ with respect to molecular conformation, lateral interactions, and dipole arrangements and how these features affect the properties and topology of the membrane surface\textsuperscript{40-44}.

There are two types of CNTs: single-walled nanotubes (SWCNTs) and multi-walled nanotubes (MWCNTs)\textsuperscript{45}; that they have three conformation:

\begin{align*}
\text{Fig. 1: DPPC and DMPC molecule}
\end{align*}

\begin{align*}
\text{Fig. 2: DPPC}
\end{align*}

armchair (n,n), zigzag (n,0) and chiral (n,m) these conformations have individual properties\textsuperscript{46-50}.

SWCNTs have been considered as the leading candidate for nanodevice applications because of their one-dimensional electronic bond structure, molecular size, and biocompatibility, controllable property of conducting electrical current and reversible response to biological reagents hence SWCNTs make possible bonding to polymers and biological systems such as DNA and carbohydrates\textsuperscript{51-57}.

**Computational Methods**

All calculations have done by ab initio at the Hartree-Fock (HF) level of theory Gaussian 98 package\textsuperscript{58}. Four basis sets have used, namely the sto-3G, 3-21G, 6-31G and 6-31G*. The geometry of DPPC, DMPC have full optimized at the RHF/6-31G*, 6-31G, 3-21G and STO-3G levels of the theory in the gas phase\textsuperscript{59-61}. 
Fig. 3: The charge changing due to each hydrophobic chain of the DPPC

Fig. 4: The electron density of the nanotube

Fig. 5: The Nano tubes in various solvent of water and methanol
The most important dihedral angle of these molecules (DPPC and DMPC) is chosen and scanned within 180 degrees rotation. In this manner after the optimization of total molecules, important dihedral angle of these molecules has rotated 15 degrees at every time.

The effects of the solvent polarization are described in terms of proper QM operators to be added to the Hamiltonian of the isolated system then, the salvation calculations have performed using Onsager method at HF/6-31G*. For Onsager model, it does require values of volume (\(a_0\)) of the molecule and the dielectric (\(\epsilon\)) of solvent. The volume of DPPC and DMPC molecules was obtained using the “volume” keyword. The Onsager-SCRF was that it permitted one to directly exploit almost all of the computational facilities of the Gaussian packages. For this reason, and for its very limited computational cost, it is still in use by people not requiring an accurate description of salvation effects but just a guess or a qualitative correction to the values obtained for the isolated molecule. Users must be aware of the limitations of the approach, of the unphysical deformation of the solute charge distribution it may induce, and of other shortcomings specific of the approach, such as the lack of salvation for solutes with zero permanent dipole.
In the Onsager method, the solute molecule is placed in a spherical cavity of radius $a_0$ surrounded by a continuum with constant dielectric properties\(^{67}\). A dipole in the molecule will induce a dipole in the medium, and the electric field applied by the solvent dipole will in turn interact with the molecular dipole leading to net stabilization. The molecular geometrics have obtained via HF/6-31G* level optimization in the gas phase and have rotated and then any one separately have been placed in the solvents\(^{67, 68}\).

### RESULT AND DISCUSSION

Dipalmitoylphosphatidylcholine (DPPC) and dimyristoylphosphatidylcholine (DMPC) molecules have chosen as starting structures for gas phase (Fig1).

The DPPC and DMPC zwitter-ionic are found to be unstable in the gas phase when have optimized at HF/3-21G, 6-31G and 6-31G* level. The obtained result from optimization and stabilization parameters are shown in Table 1.
